

**Development of techniques to Calibrate Digital
Cameras and Derive Basic and Advanced
Visibility Metrics from Digital Imagery
(or back to the future)**

John V. Molenaar

IMPROVE Steering Committee Meeting

Acadia National Park

7-27-05

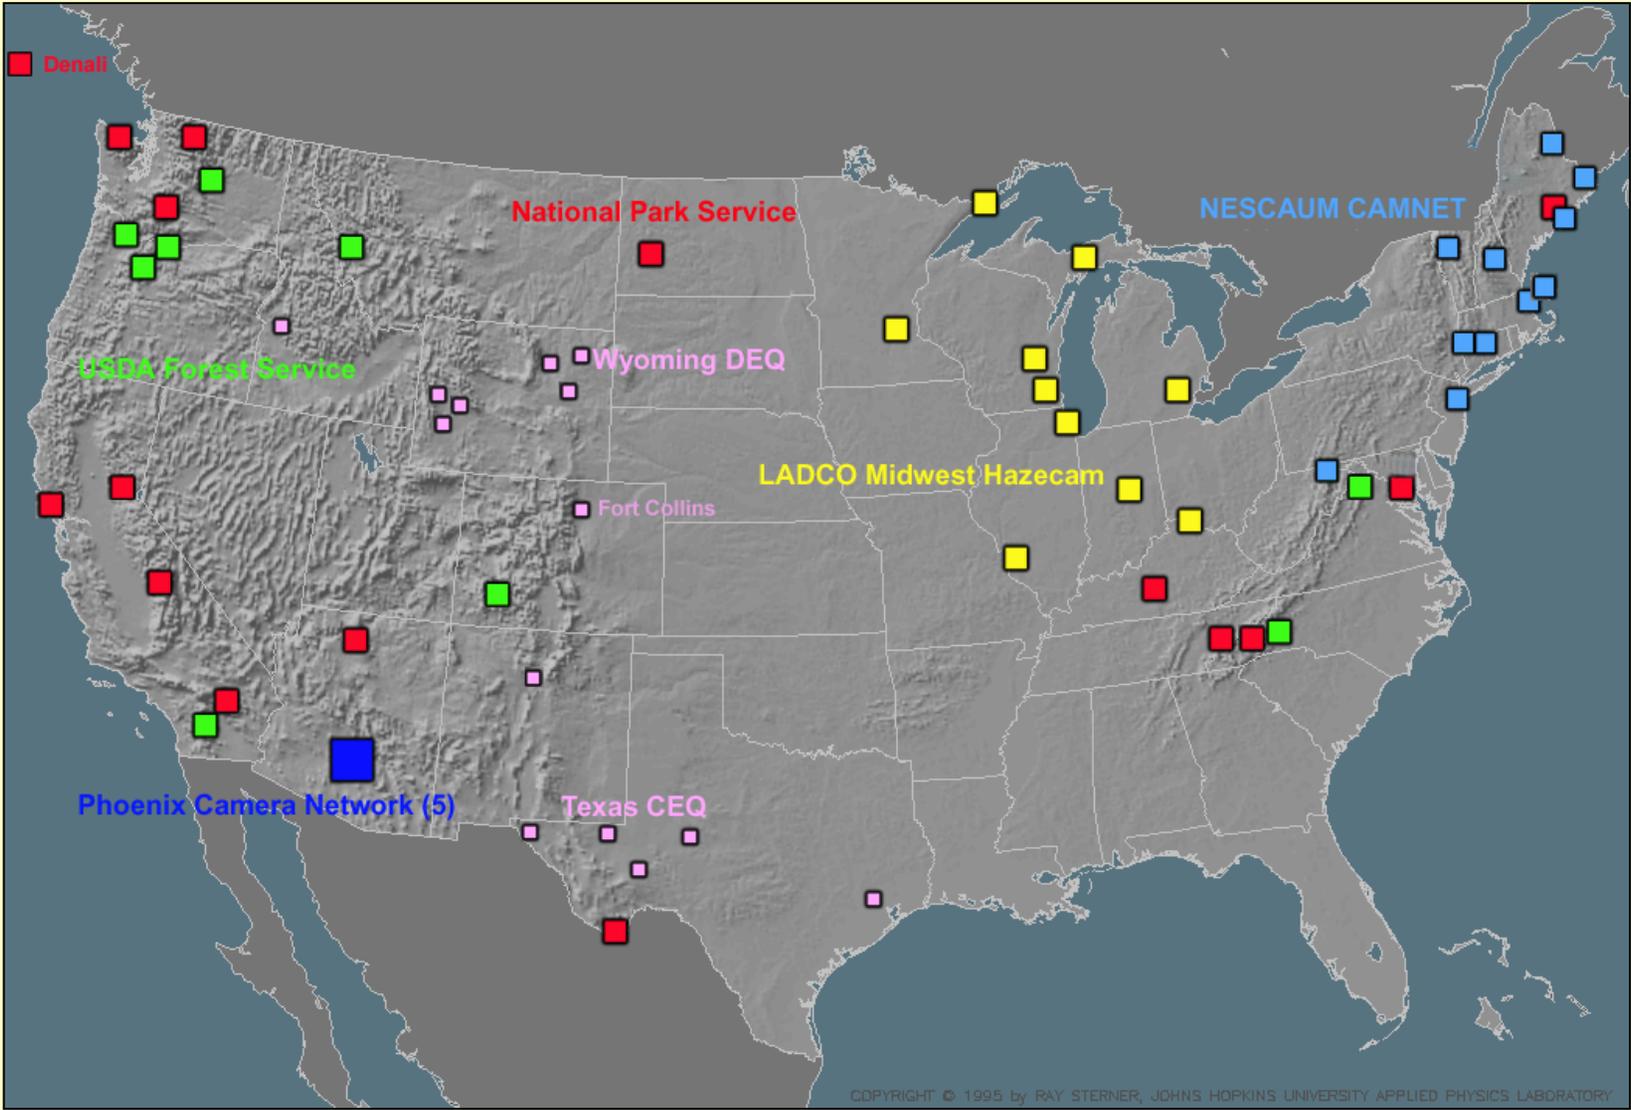

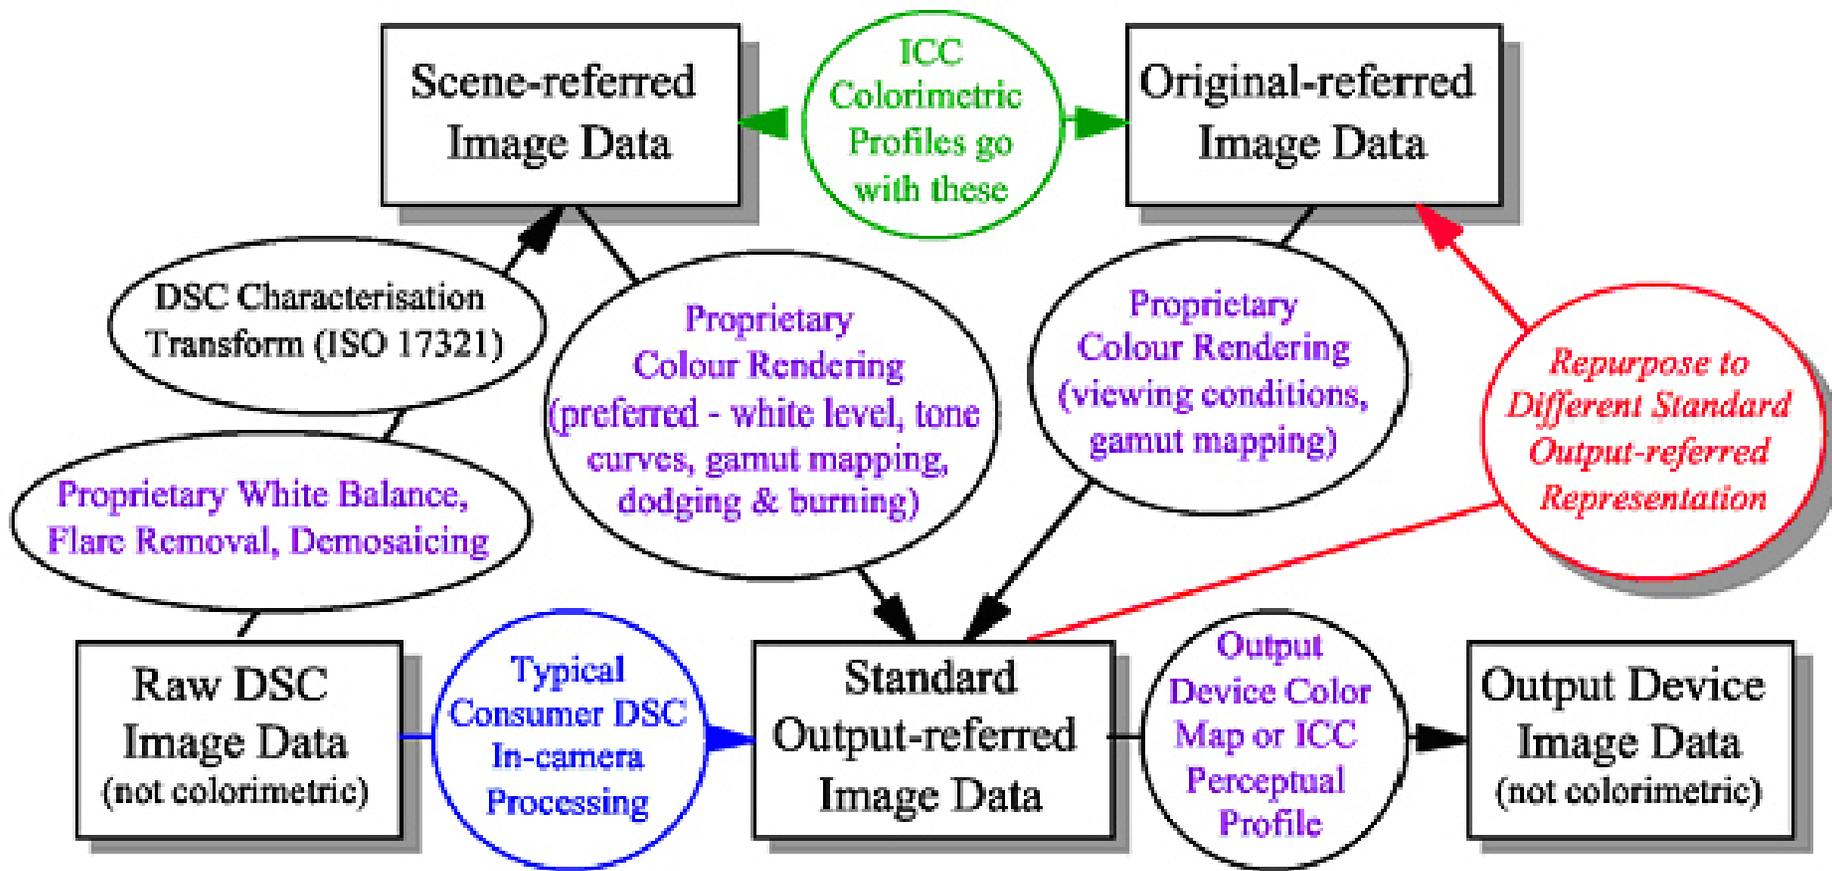

Image Preprocessing

- **Digital Camera Characterization**
- **Image Registration**
- **Clear/Uniform Sky Identification**

Digital Camera System (DCS) Image Flow

DCS Characterization

- MacBeth Digital ColorChecker SG
- Photo Research 650 Spectroradiometer
- D65 Daylight light source
- Olympus C-730 Digital Camera
- LOTS of TIME

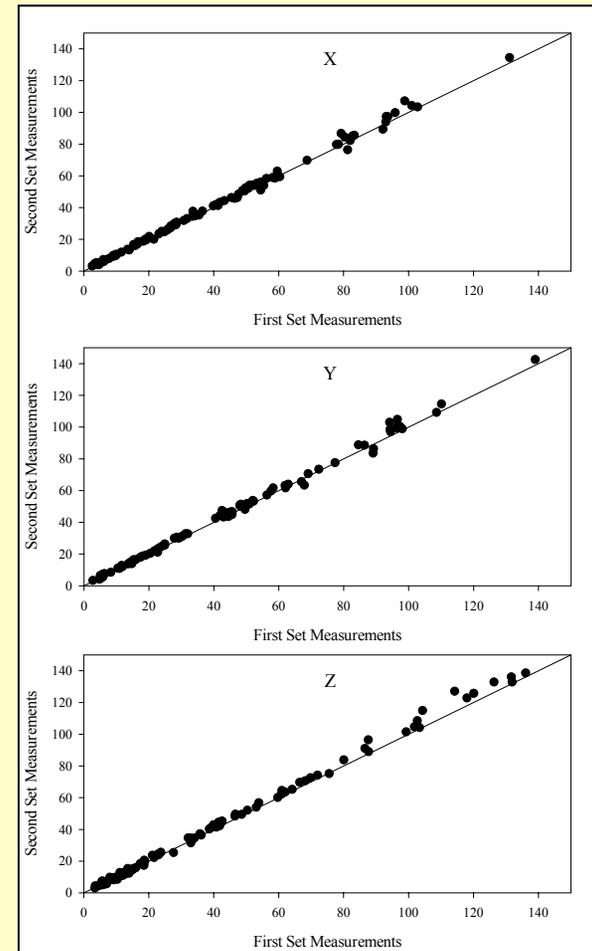

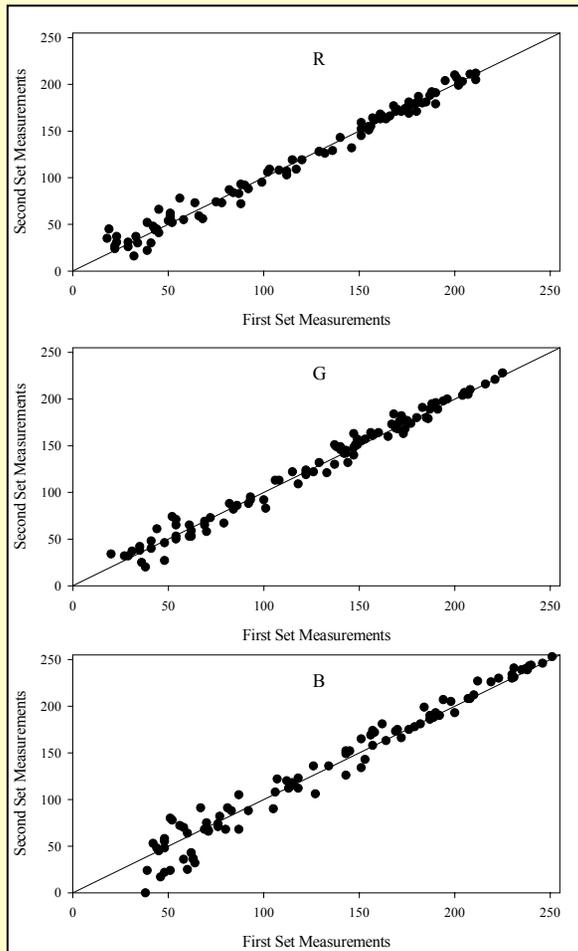

Digital ColorChecker® SG

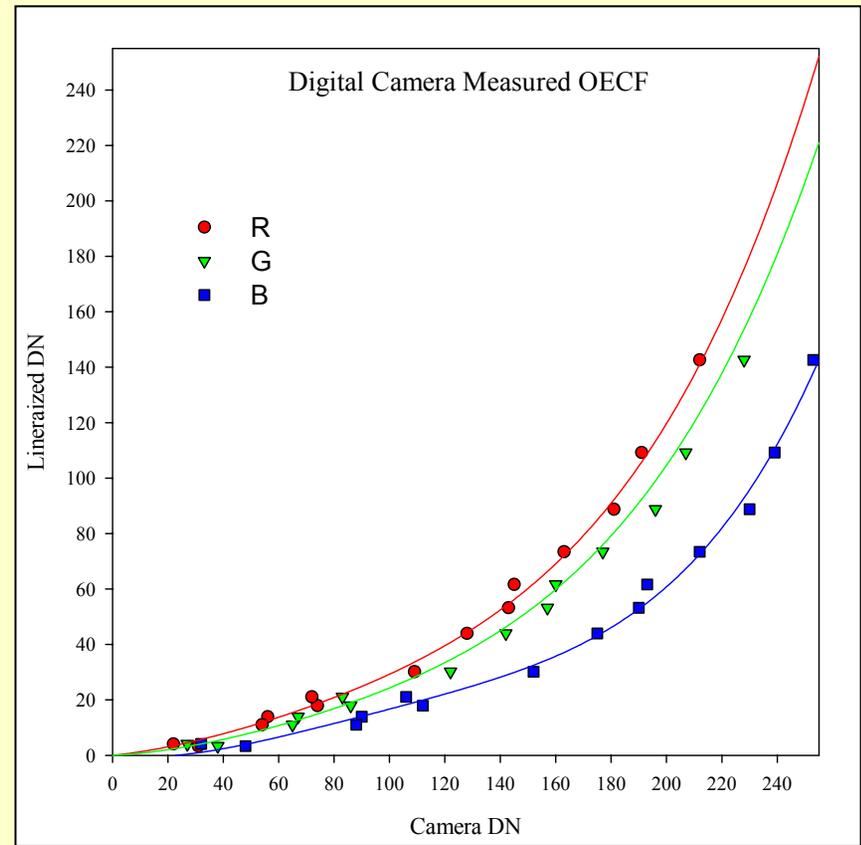

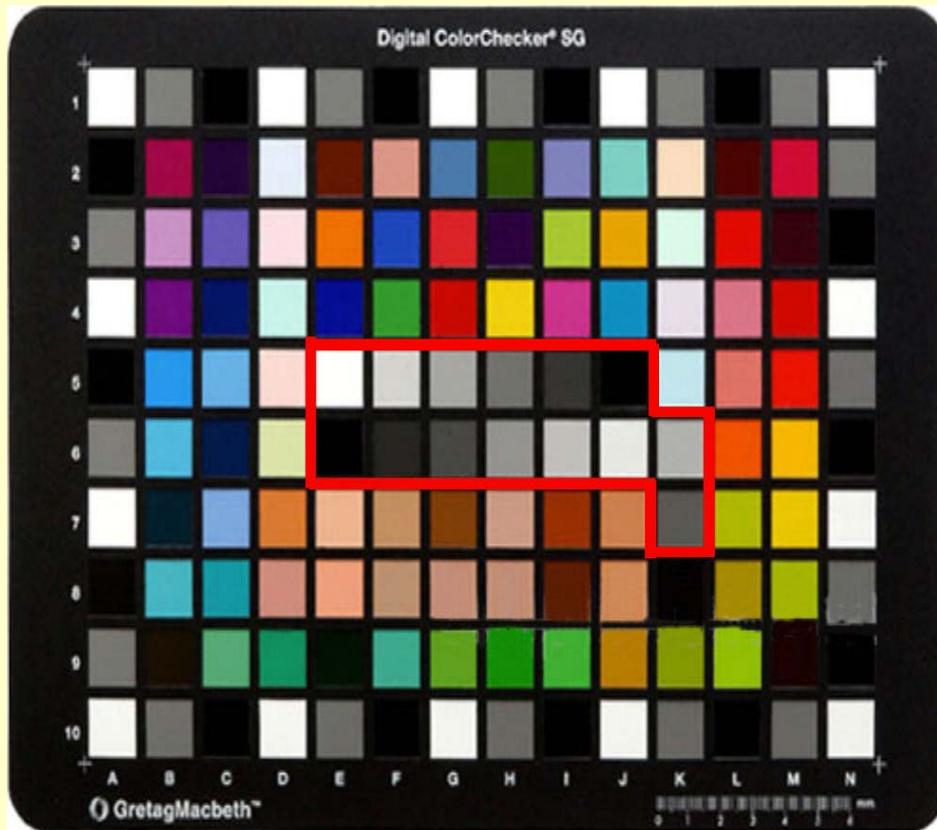

GretagMacbeth™

0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 mm

Measurement Repeatability

Opto-electronic Conversion Function

Two sets of measurement triplets from MacBeth CC patches (n=24)
Linearized RGB from digital camera and XYZ from spectroradiometer

$$V = \begin{pmatrix} R1 & G1 & B1 \\ R2 & G2 & B2 \\ \cdot & \cdot & \cdot \\ Rn & Gn & Bn \end{pmatrix} \quad P = \begin{pmatrix} X1 & Y1 & Z1 \\ X2 & Y2 & Z2 \\ \cdot & \cdot & \cdot \\ Xn & Yn & Zn \end{pmatrix}$$

$$P = AV$$

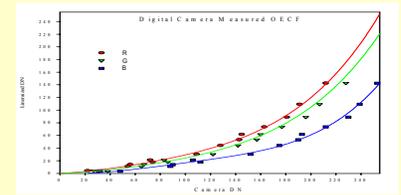

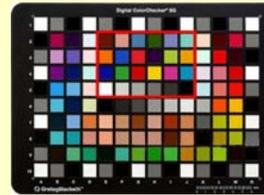

$$A_X = (V^T V)^{-1} (V^T P_X)$$

Polynomial Solutions

- $X = a_1R + a_2G + a_3B$ (3 x 3)
- $X = a_1R + a_2G + a_3R + a_4RG + a_5RB + a_6GB$ (3 x 6)
- $X = a_1R + a_2G + a_3R + a_4RG + a_5RB + a_6GB + a_7R^2 + a_8G^2 + a_9B^2$ (3 x 9)
- $X = a_1R + a_2G + a_3R + a_4RG + a_5RB + a_6GB + a_7R^2 + a_8G^2 + a_9B^2 + a_{10}1$ (3 x 10)
- $X = a_1R + a_2G + a_3R + a_4RG + a_5RB + a_6GB + a_7R^2 + a_8G^2 + a_9B^2 + a_{10}1 + a_{11}RGB$ (3 x 11)

DCS Characterization

- Measure all 96 patches
- Linearize RGB data with 14 step grayscale
- Calculate coefficients using 24 CC patches for possible polynomials
- Calculate predicted XYZ for all 96 patches
- Convert measured and predicted XYZ to Lab
- Calculate deltaE94 between measured Lab and predicted Lab
- Determine which polynomial has least error

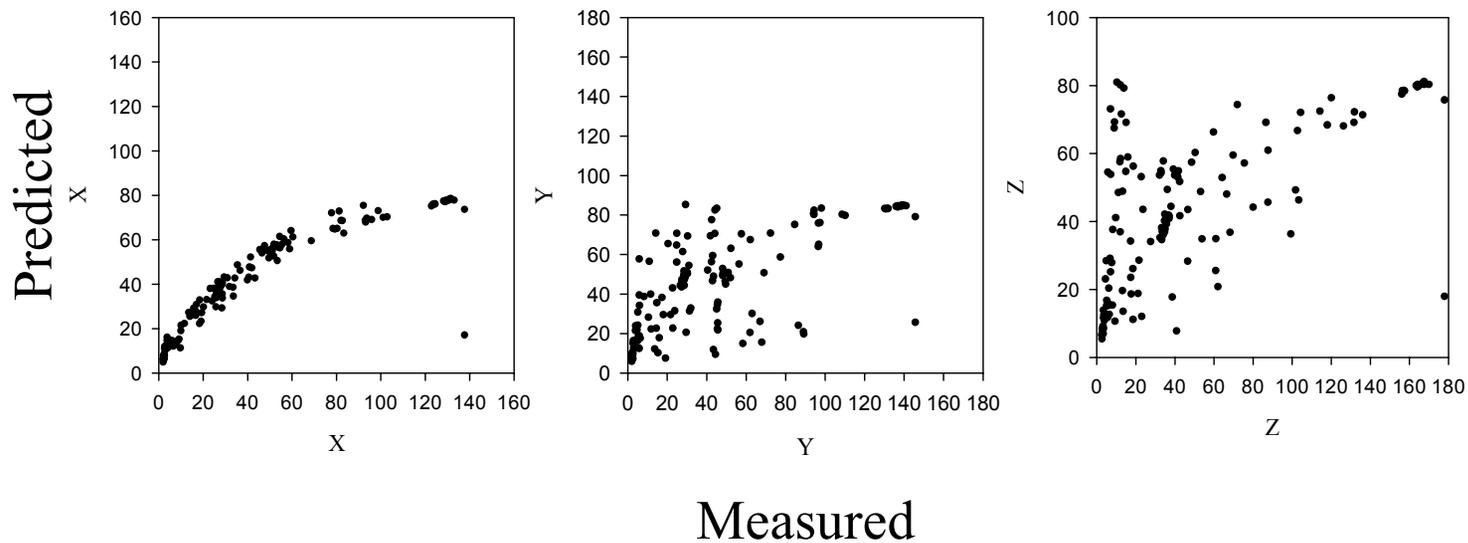

$$A = (N^T N)^{-1} (N^T P)$$

$$(XYZ) = A(RGB)$$

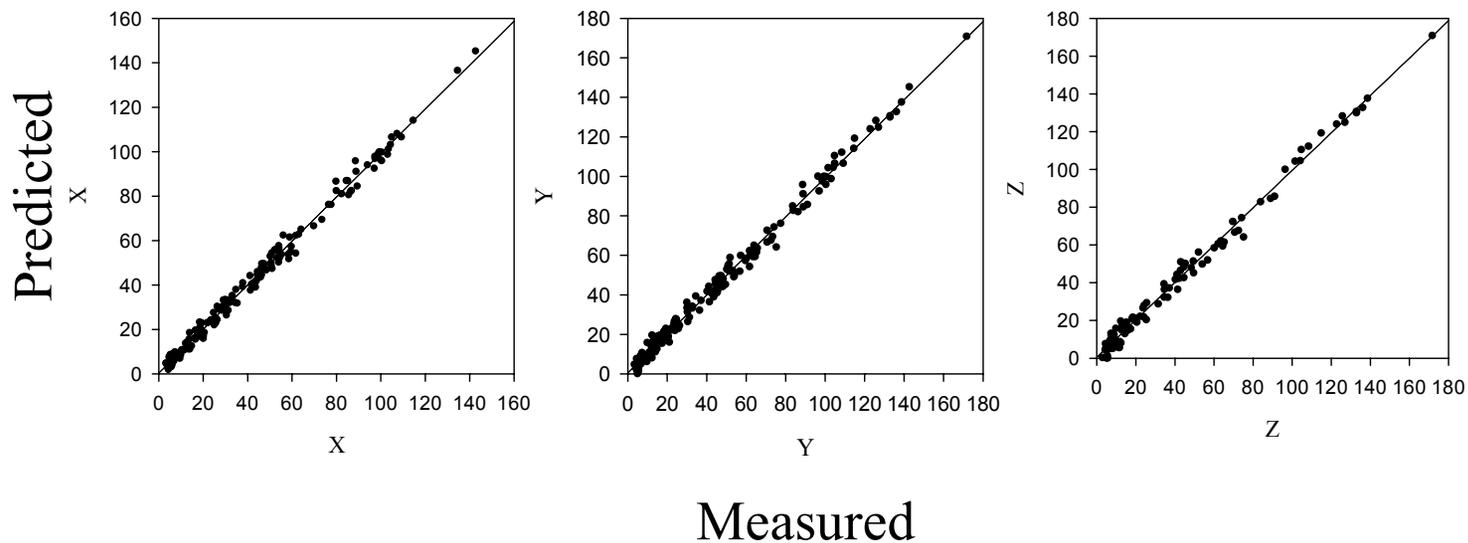

$$(Lab) = B(XYZ)$$

$$\text{deltaE94} = (\Delta L^2/k1 + \Delta a^2/k2 + \Delta b^2/k3)^{1/2}$$

3 x 3 (Linear) Polynomial Regression

3 x 11 Polynomial Regression

deltaE94: Measured vs. Predicted

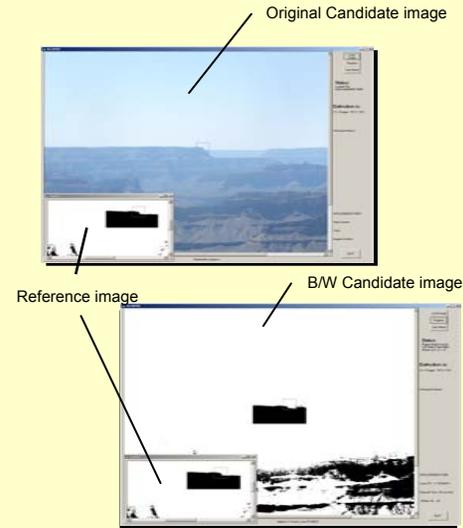

Coeff.	Avg	Max	Min	White	Mid-Gray	Black
3 x 3	5.2	23.7	0.7	3.3	17.1	2.2
3 x 6	4.4	23.0	0.6	0.6	16.8	2.9
3 x 9	6.4	25.2	0.6	16.7	19.4	2.7
3 x 10	3.7	13.0	0.2	0.2	9.9	1.6
3 x 11	3.8	11.5	0.1	0.1	12.1	1.5

Image Preprocessing

- **Digital Camera Characterization**
- **Image Registration**
- **Clear/Uniform Sky Identification**

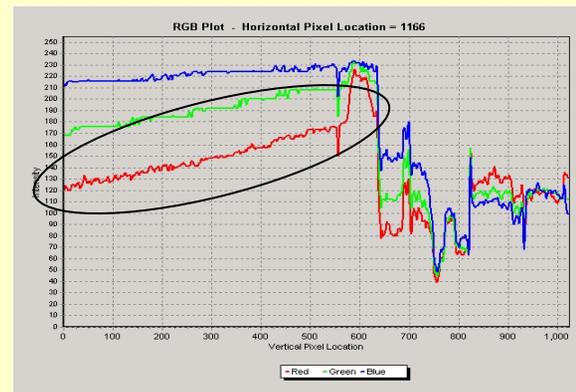

Registration

- Each image is registered to account for camera movement or misalignment. Registered images are necessary for target/sky contrast, as well as other image metrics.
- Compares B/W version of candidate image to reference B/W image pixel by pixel. B/W binary comparison is used to eliminate shading and color influences.
- Candidate image “walks” one pixel at a time in a spiral pattern until the 50 by 50 pixel test areas in the candidate and reference images have a 98% match.
- Results of registration are horizontal and vertical offsets. They are save in the image database for use by the image metric algorithms. The original images are not affected.
- The registration target must be close enough to be visible for all air quality conditions, but be far enough away to minimize parallax float problems (small registration error causing large errors in scene element locations).

Clear Sky Identification

- Each image is tested for cloud free (clear sky) conditions. Clear sky conditions are necessary for target/sky contrast, as well as other image metrics.
- Five vertical regions are scanned for discontinuities in the red band of the RGB color triplet .
- This technique correctly identifies cloud free images 95% of the time.
- Not possible to determine if images or scenes are completely cloud free because entire sky is not visible.

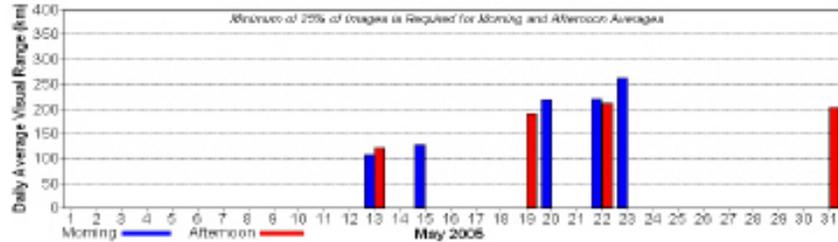

Calculation of Visual Air Quality Metrics

- apparent target (C_r) contrast
- b_{ext} from apparent target contrast
- image difference metrics:
 - pixel-by-pixel ΔE
 - image average ΔE
- image difference metrics based on Human Visual System (HVS) models: S-CIELAB, dcTune, iCAM, others

Grand Canyon National Park

b_{ext} from Digital Images vs. b_{sp} from Nephelometer

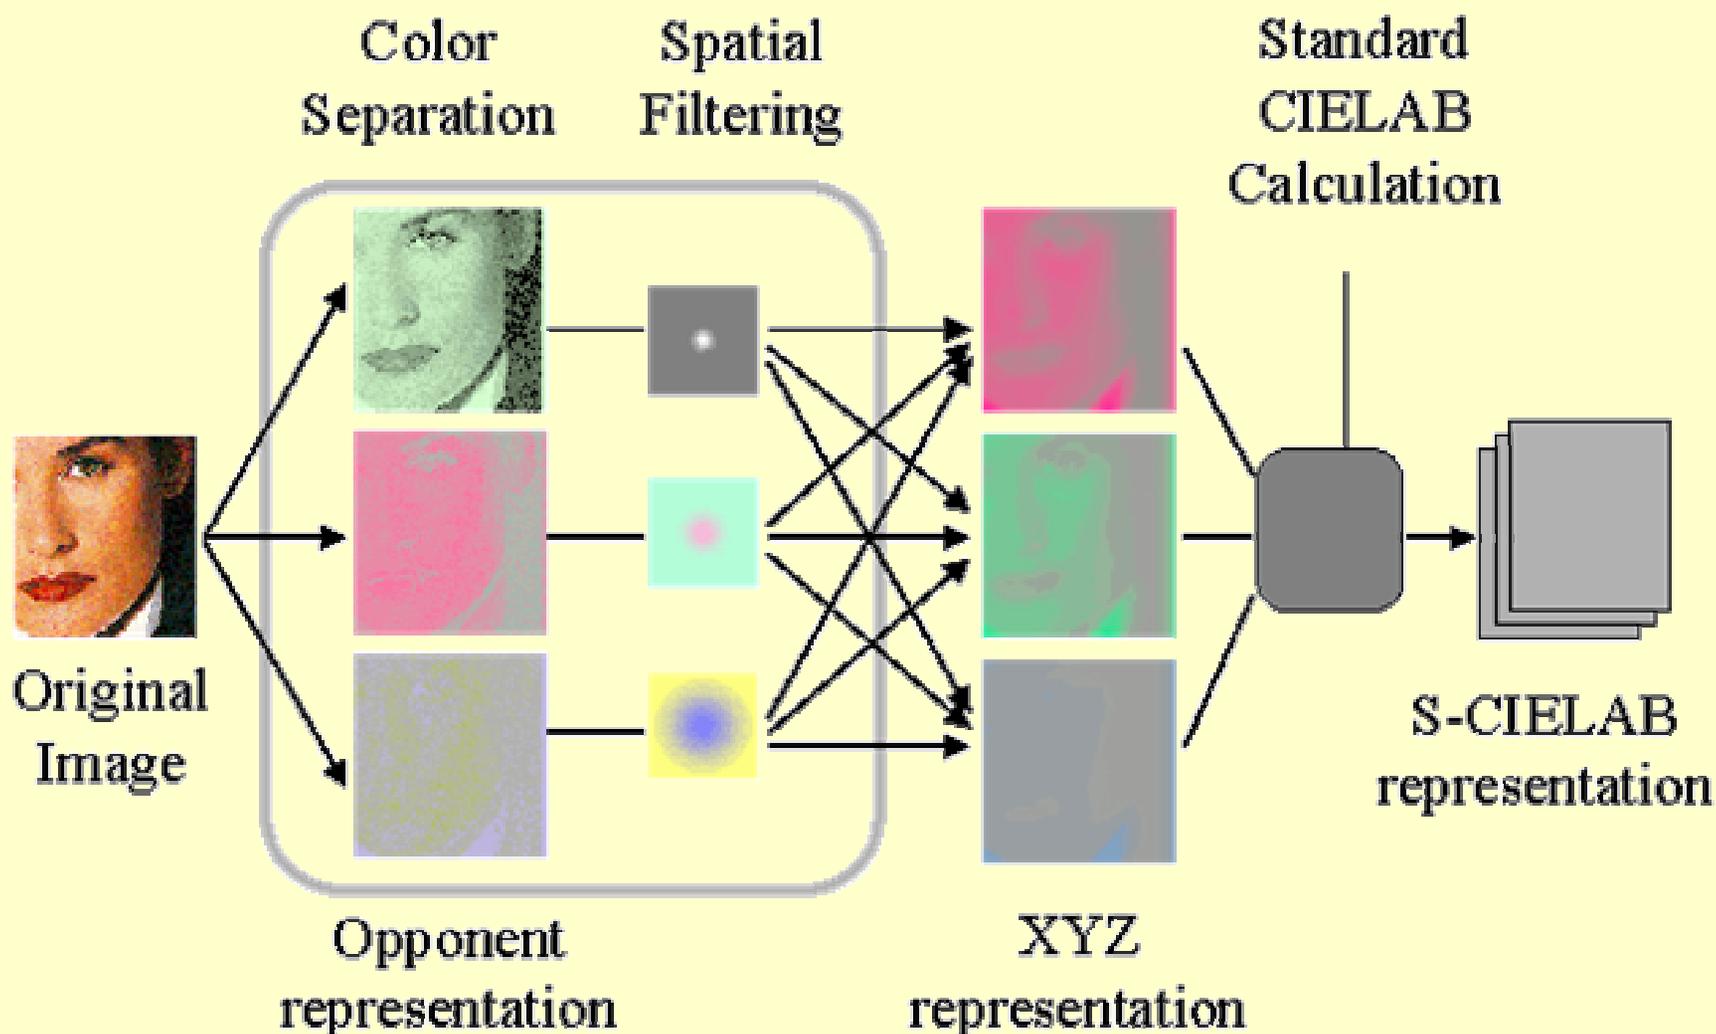

1/1/2005 – 6/8/2005

Calculation of Visual Air Quality Metrics

- apparent target (C_r) contrast
- b_{ext} from apparent target contrast
- image difference metrics:
 - pixel-by-pixel ΔE
 - image average ΔE
- image difference metrics based on Human Visual System (HVS) models: S-CIELAB, dcTune, iCAM, Sarnoff, and MANY others

S-CIELAB Model

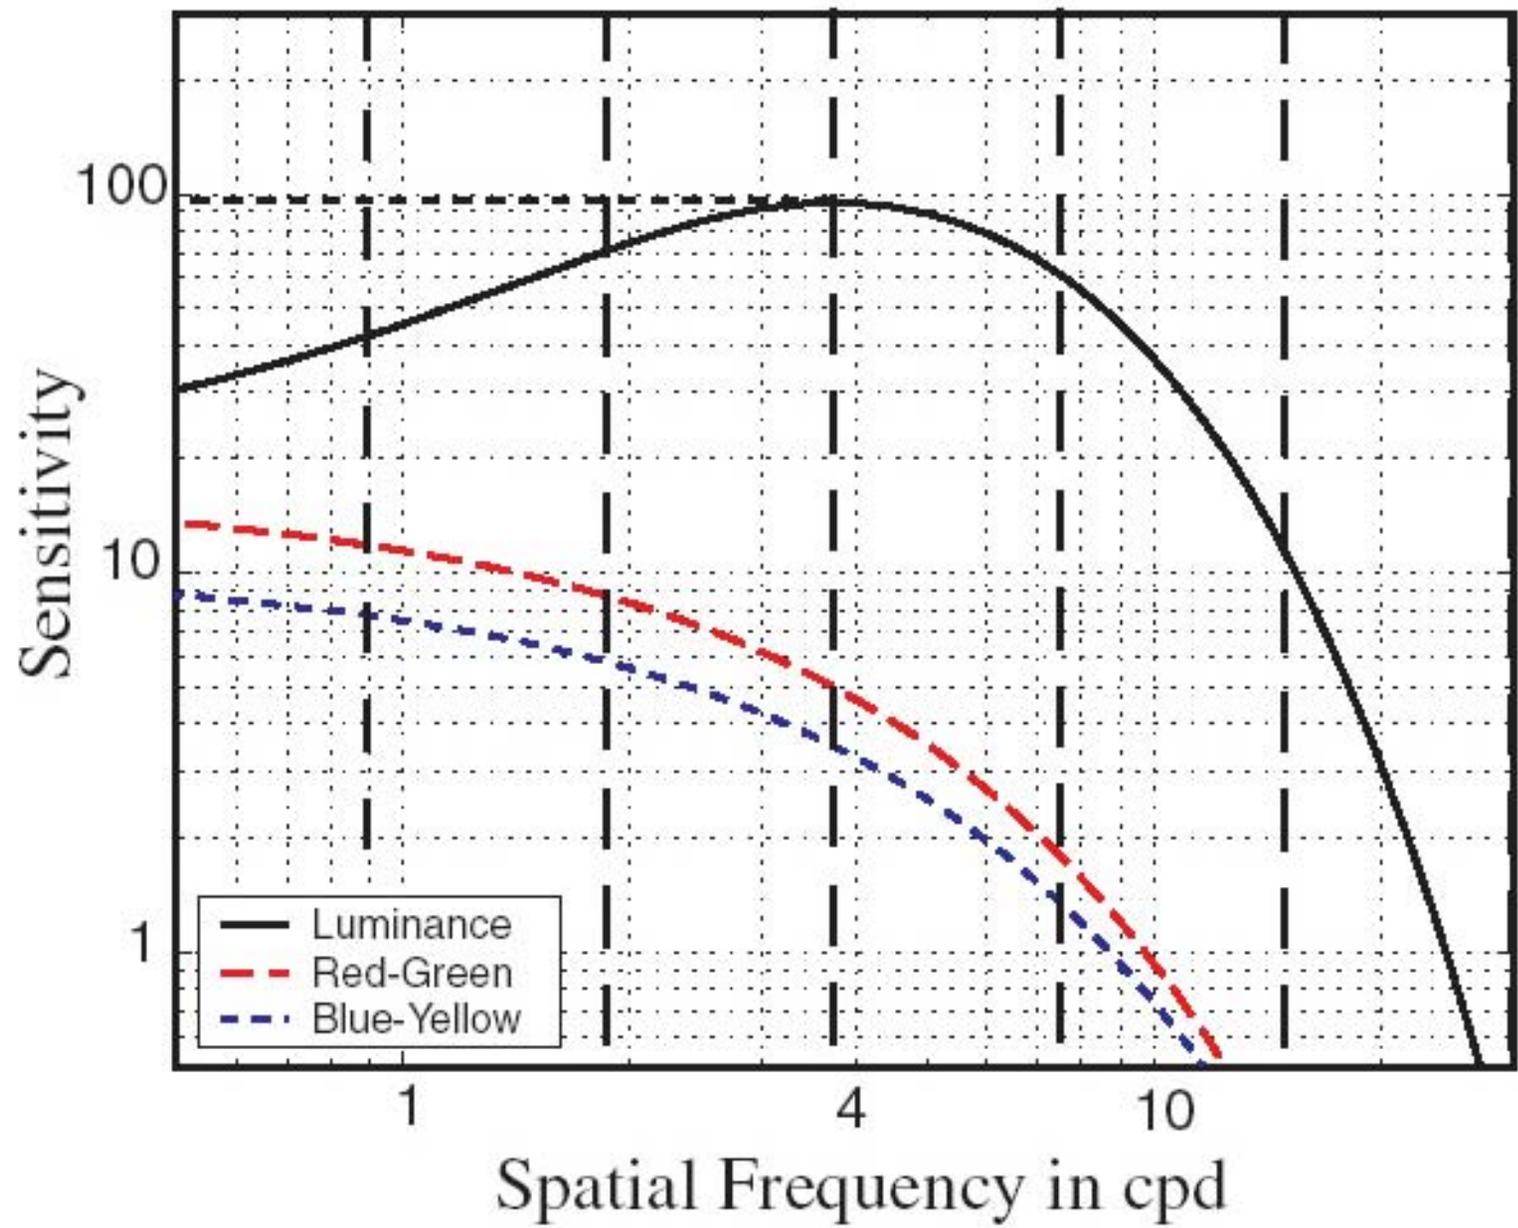

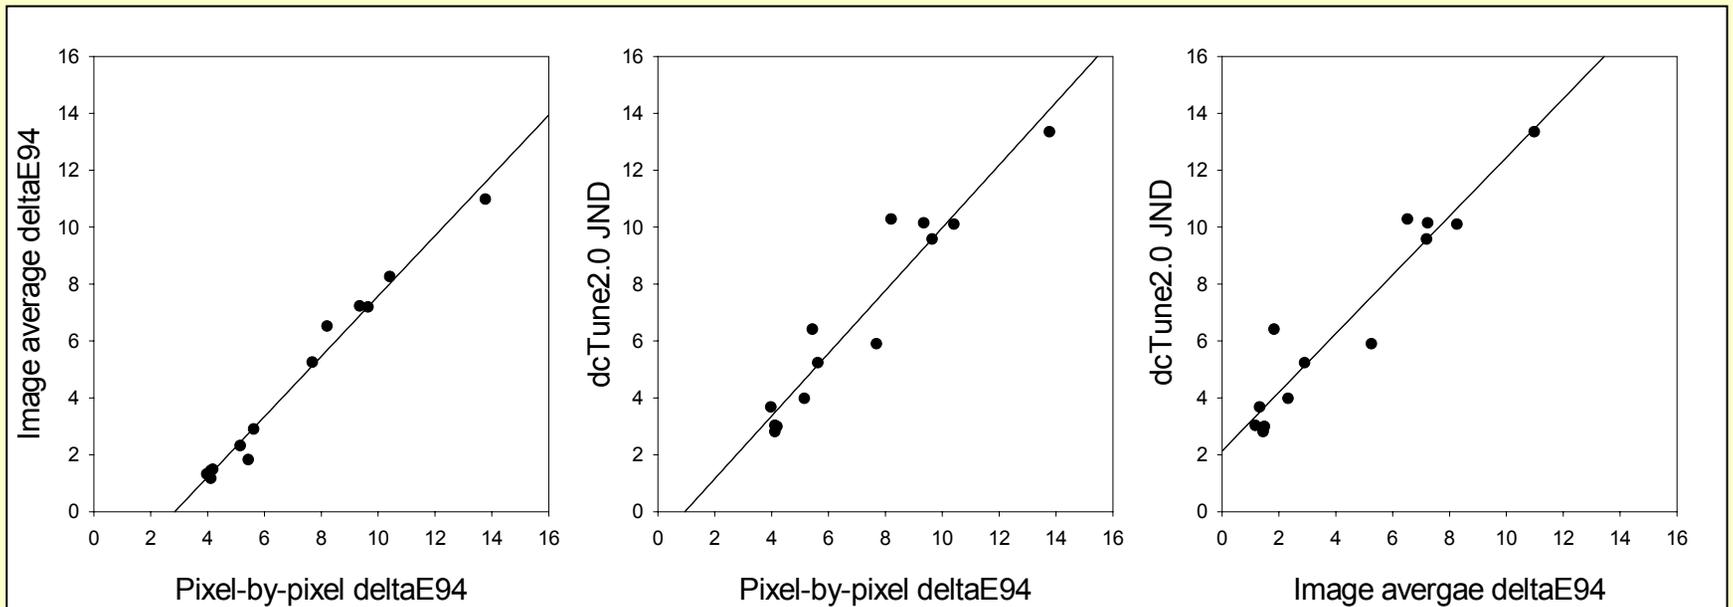

Image Modulation Depth

$$I_{m(rgb)} = \frac{1}{(n-1)\overline{E_{(rgb)}}} \left[\sum_{i=1}^n (E_{i(rgb)} - \overline{E_{(rgb)}})^2 \right]^{1/2}$$

$$ModDepth = \left(I_{m(r)}^2 + I_{m(g)}^2 + I_{m(b)}^2 \right)^{1/2}$$

GRCA WinHaze Images

Current Status

- Digital images can be automatically registered, and categorized for further analyses
- Digital cameras can be reasonably characterized allowing the calculation of various image metrics
- Tests indicate that for “clear sky” images these various metrics can be related to onsite optical measurements

Current Status

- Operational at Grand Canyon NP, Great Smoky Mountains NP, and Phoenix, AZ providing Automatic Monthly and Semi-automatic Quarterly summaries of b_{ext} and Visual Range
- Is available for other locations depending on funding by clients

On going (ARS Funded) Work

- Automate characterization hardware
- Examine and include flare and image plane uniformity corrections
- Test various digital cameras by characterizing the systems, take simultaneous images of scenic vistas, calculate and compare visual air quality metrics calculated from different cameras for same scene
- Development of additional data products
